

The Human Immune System

The immune system is the body's defense against infections and disease.

It consists of two main parts: the innate immune system and the adaptive immune system.

White blood cells called lymphocytes are key players in immunity.

B cells produce antibodies that target specific pathogens.

T cells directly attack infected cells and help coordinate immune responses.

Vaccines work by introducing harmless antigens to train the immune system.

This allows the body to mount a faster response if the real pathogen is encountered.
